

NEMA MG P1-2020

*Prioritization with a Sense of Proportion: Anhydrides
MHHPA and HHPA under the European REACH Directive*

DISCLAIMER

The Standards or guidelines presented in a NEMA Standards publication are considered technically sound at the time they are approved for publication. They are not a substitute for a product seller's or user's own judgment with respect to the particular product referenced in the Standard or guideline, and NEMA does not undertake to guarantee the performance of any individual manufacturer's products by virtue of this Standard or guide. Thus, NEMA expressly disclaims any responsibility for damages arising from the use, application, or reliance by others on the information contained in these Standards or guidelines.

Introduction

The European Committee of Manufacturers of Electrical Machines and Power Electronics (CEMEP) and the National Electrical Manufacturers Association (NEMA) of the U.S. supply the majority of motors, generators, transformers, switchgear, and other critical electrical products placed in operation in the EU market. The two groups respectfully offer the following comments regarding the European Chemical Agency (ECHA) proposal to add Methylhexahydrophthalic Anhydride (MHHPA) and Hexahydrophthalic anhydride (HHPA) to the Substances of Very High Concern (SVHC) Candidate List under European Registration, Evaluation, Authorisation and Restriction of Chemicals (REACH) regulation.

Background

The European REACH authorization process pursues three equivalent targets: smooth functioning of the European internal market, sufficient control of the risks from SVHC, and successive substitution of SVHCs with appropriate alternative substances or technologies, if they are economically and technically feasible.

Altogether, REACH aims to ensure high-level protection of human health and the environment. By doing so, it aims to promote innovation and improve production conditions that help prevent harmful consequences of SVHCs through appropriate risk management measures.

Position Statement

The electro-product industry objects to the prioritization of the two anhydrides MHHPA and HHPA and their subsequent inclusion into Annex XIV following the European REACH authorization procedure. While manufacturers of electrotechnical products support the goal of replacing SVHCs successively through appropriate substitution and technological innovation, we firmly believe that the ECHA decision on anhydrides is premature and lacks a sound scientific basis. We recommend that a risk management option analysis (RMOA) is conducted that includes technical guidance from experts within the manufacturing industry.

Decisions concerning adequate and proportionate risk management options for SVHCs must be made as early as possible through a transparent process in association with industry. This analysis should be performed before the preparation of an Annex XV 2 dossier to ensure that the dossier correctly assesses the actual risks associated with different applications of the substance under review. Only in this way can the most appropriate risk management options be defined.

The undersigned organizations further contend that potential risks associated with the two anhydrides MHHPA and HHPA are already mitigated and that no commercially available alternatives exist for their critical applications. A decision to prioritize the anhydrides MHHPA and HHPA at this time would inevitably result in the economic disruption of leading industry suppliers.

In summary, the undersigned organizations recommend that a more detailed analysis of the particular applications of these substances is conducted to determine risks and appropriate mitigation actions accurately. A broad-based “blanket” prioritization is premature and does not reflect the reality of how these compounds are used in the production arena.

Substance Information

MHHPA and HHPA are key building blocks in the production of epoxy resin-based insulating materials, which are widely used in electrical equipment. The proper function, as well as the electrical safety of this equipment, is largely dependent on the insulating material containing the epoxy resin.

Electrical products and systems, in turn, are vital components of a successfully operating infrastructure for energy generation and distribution. Efficient electricity networks require equipment such as electrical switchgear, switching devices, and transformers for voltage transformation and energy distribution, as well as for the connection and disconnection of parts of the supply network (substations).

Electrical motors and generators that control energy conversion and generation are essential to achieving policy objectives related to energy transition and resource efficiency and are backbones of the worldwide industry.

In addition to their use in electrical infrastructure, epoxy resins are used extensively for insulation in automotive electrics and shipbuilding as well as for encapsulations in lighting technology (LEDs) and IT equipment (fiber optics).

Economic and Technical Importance

Energy-efficient insulating materials containing MHPA and HHPA have been used successfully for decades in the applications mentioned above. Within the manufacturing process, the anhydrides react chemically with the epoxy resin so that no free anhydrides are present in the finished product. In this sense, anhydrides are described as intermediates in the production process.

Epoxy resin insulation has been the focus of considerable research activity for many years and guaranteed long-term security of supply of the electroindustry with the anhydrides mentioned above is necessary. At this time, industrial manufacturers have tested and found no technically reliable and economically feasible substitutes for MHPA and HHPA are available for their applications in the electrical sector. Although other curing agents are available for epoxy resins, they do not provide the process capability or required combination of mechanical, thermal, and electrical resistances necessary for safe and reliable motor performance, and they are not sufficiently durable for outdoor use. Furthermore, insulating materials based on other chemical substances fail to meet these requirements.

Restrictions on the use of anhydride hardeners will impose a large burden on companies that manufacture insulating materials for critical electrical products. This would constrain innovation among companies and thus adversely affect energy generation plants and the extension of power distribution.

Even if alternatives to anhydrides are discovered, they must be proven to meet rigorous safety requirements and quality certification Standards before approved for widespread use in power generation and distribution, not to mention other central industrial competence areas such as aerospace, shipbuilding, mining, and automotive engineering. Attaining special approvals for these applications require vast technical investigations that may last many years, if not decades.

Safety Aspects and Risk Management

Anhydrides are exclusively used as monomers and, therefore, as intermediates within the production chain for industrial appliances.

Moreover, finished insulation products based on cured epoxy resins do not contain free anhydrides and therefore are safe to use. In the last decade, manufacturer initiatives and regulatory requirements have led to advancements in the area of occupational safety and risk reduction as well as optimization of technical properties and processing technology. Processing is carried out per the requirements established by safety data sheets, following worker protection regulations, including medical surveillance.

The respiratory tract sensitizing properties of anhydrides have been recognized since the 1990s. As a consequence, the manufacturing industry introduced safety precautions for the handling of anhydrides (as required by the safety data sheets). Extensive technical, organizational, and personal protective

measures (e.g., local exhaust ventilation and personal respiratory protections) are universally present in today's epoxy processing facilities. All used materials are processed, whenever possible, in closed systems. The proper application of occupational health, safety, and environmental protection measures are reviewed periodically by dedicated national authorities and by the Labour Inspectorate.

As a result of these procedures and regulatory requirements, the risk of unintentional exposure to anhydrides in state-of-the-art production facilities is minimal.

In cases in which sensitization (e.g., asthma, rhinitis, or conjunctivitis) has occurred despite the health and safety measures mentioned above, the industry-standard practice is to provide alternative jobs to affected workers, so that contact with these substances no longer occurs. In verifiable cases (see dossier from ECHA), the resolution of all symptoms has been reported.

§

The National Electrical Manufacturers Association (NEMA)

The National Electrical Manufacturers Association (NEMA) represents nearly 325 electrical equipment and medical imaging manufacturers that make safe, reliable, and efficient products and systems. Our combined industries account for 370,000 American jobs in more than 6,100 facilities covering every state. These industries produce \$124 billion in shipments and \$42 billion in exports of electrical equipment and medical imaging technologies per year.

About CEMEP

CEMEP is the European Committee of Manufacturers of Electrical Machines and Power Electronics, representing an industry with a market value of € 6.3 billion and 130,000 employees. The Members of CEMEP are the National Associations in Europe, representing manufacturers of electric motors, variable speed drives, and uninterruptible power supplies.

This organization allows industry to coordinate actions at the European and International level, with the main topics being: market evolution, standardization, regulation, promotion, and connection with other products and professional groups.
